FINITE ELEMENT ANALYSIS OF SCARFED LAP RIVETED AND WELDED JOINT WITH DIFFERENT LAP ANGLE

MS. NITISHA ACHMELWAR

Department of Mechanical Engineering, Jagadambha College of Engineering & Technology.

ABSTRACT

Load bearing capacity and fatigue tests will be carried out between Scarf lap riveted joint and Scarf lap welded joint with different lap angle. Both experimental and computational studies are to be done and the results will be validate The fabrication of the Scarf lap riveted joint and scarf lap welded joint will be done and tested on Universal Testing Machine (UTM) after that the Finite Element Analysis with ANSYS will be done. After introducing the lap angle between the faying surfaces the fatigue test and load bearing of joint will be seen. There may be possibility of increasing the fatigue life and the joints may be reliable for the structure designs. The objectives of this project is to compare simple lap riveted and welded joints with scarf lap riveted and welded joints introducing with different lap angles and to find best suitable joint among scarf lap rivet and scarf lap weld on the basis of analysis.

Keywords— Scarf lap riveted joint, Scarf lap welded joint, Lap angle, Simple lap riveted joint, simple lap welded joint.

INTRODUCTION

Many researches focus on regular lap joint those are commonly used in fuselage and airfoil. In this paper we are introducing the scarf lap joint with different lap angle which is introduced into faying surfaces which is rarely have been seen and reported. Various researches have been done on the scarf lap joint with different lap angle on its fatigue performance, for the structures but the design of details and fatigue performance are not readily available in literature. The Scarf lap joint is advantageous over the other lap joints. The important feature of Scarf lap joint is the lap angle, which has the influence on its fatigue performance also it is effective in load transfer. Consequently stress concentration reduced remarkably.

The experiments of joints have been studied by many scholars they proposed the joints with various tests. There they have studied and investigated the fatigue and fracture behaviour for Scarf lap joint with different lap angle. In previous studies it was found that the author has predicted the results with Smith Watson Method (SWT) and Wang Brown Method (WB) have structure reliability in designs. The SWT method was achieving better accuracy.

NECESSITY: Scarf joints have been found to exhibit the highest structural efficiency because joint eccentricities (which act as stress raisers) are minimized in the loading path and a more uniform stress distribution is obtained across the joint. This however, comes at a cost due to the fact that current scarf repair technology utilizes angles of 1 and 3 degrees, which over a thick section can cause a large waste due to removal of large amounts of undamaged parent material. As the thickness of the composite structure increases the repair size becomes much larger and the amount of undamaged material required to be removed also increases greatly. With

this in mind research is being undertaken to better understand changes in scarf angle and how to optimize their size and load transfer efficiency. To achieve this, basics of load transfer in a scarf joint must be understood and once these basics are covered, computer FEA and physical testing can be used to study different joining techniques. The traditional scarf jointing techniques cannot match the strength and stiffness of a single member of the same dimensions. Due to their low bending capacity it has been historically understood that a scarf joint within a frame should be located where the bending moments are low in order to minimize the deflection. This initiative has carried through to modern design of traditional frames where the joint can be found either over a post or a brace. The amount of taper with a scarf joint is usually stated as the ratio of the thickness of the joining members to taper. Scarf joint widely used as high performance structural joint for various applications because of its high specific strength and stiffness.

OBJECTIVE: Structural Joint phenomena of Scarf joint are very important aspect in industrial sector, social sector and in every surroundings. So, it is very essential to find out in which case the joint strength is more. Scarf Joint analysis depends upon the lap angle of the joint. In this project there are two types of analysis 1) Experimental analysis 2) Computational Analysis is done on scarf lap and simple lap joint. The aim of this project is to find out the best suitable joint between scarf lap riveted joint and scarf lap welded joint.

THEME: The scarf Joints are used for effective analysis in all engineering structures, where strength is a prime concern. The project work has to be done to find out suitable scarf joint under tension and compression test. Experimental analysis is to be done for finding out optimum values of joint and stresses induced to calculate its strength and the result obtained has to be validated by computational analysis. (ANSYS 14.5)

SYSTEM DEVELOPMENT

Design Theory

The Stresses in the Structure Joints are complex. Differences in mechanical properties of the adherends induce complex stresses states in the joints even where the loading superficially looks relatively simple. It has been common to use stress criteria based on the measured strength of joints to the required area of joints. Generally the maintenance and repairs of structures joints is more complex than the case of conservative structures and advanced techniques are demanded for the damage and repairs of joints.

Scarf Joint

Determination of the maximum axial force for two pieces joined by adhesive can easily be determined using two equations that can be derived from the geometry of the problem by breaking the axial force component into a tensile force and shear force normal and parallel to the scarf joint. To specify the orientation of the inclined section pq by the angle α between the X-axis and the normal to the plane.

Fig 3.1: Stress acting on Scarf Joint

The force **P** can be resolve in two components.

Normal force **N** perpendicular to the inclined plane, $N = P \cos \alpha$

Shear force **V** tangential force to the inclined plane, $V = P \sin \alpha$

If we know the area on which the forces act, we can calculate the associated stresses

Fig 3.2: Associated Stresses on Scarf Joint

Rivet Joint:

A connection between two members which are riveted together by means of rivets. The rivets are use to make permanent fastening between the plates such as in structural work, ship building, bridges, tanks and boiler shells. The rivet joints are widely used for joining light metals.

Design Specification:

While designing the rivet joint following considerations has been taken as per design data book. The material used for flat plate and rivet is Mild Steel.

Thickness of plate $t = 6 \text{ mm}$

Diameter of rivet hole $d = 2*t = 2*6 = 12 \text{ mm}$
 Pitch length $p = 2.25*d = 2.25*12 = 27 \text{ mm}$
 Marginal pitch $m = 1.5*d = 1.5*12 = 18 \text{ mm}$

 <p>Diagram showing a rivet joint with length $L = 117 \text{ mm}$, thickness $t = 6 \text{ mm}$, width $w = 63 \text{ mm}$, pitch $p = 27 \text{ mm}$, marginal pitch $m = 18 \text{ mm}$, rivet hole diameter $d = 12 \text{ mm}$, and angle $\alpha = 2.93^\circ$.</p>	<p>$L = 117 \text{ mm}$ $\alpha = \tan^{-1} \left[\frac{6}{117} \right]$ $t = 6 \text{ mm}$ $\alpha = 2.93^\circ$ $p = 27 \text{ mm}$ $m = 18 \text{ mm}$ $d = 12 \text{ mm}$</p>

Fig: Design Specification for rivet joint.

Welded Joint

A welded joint is a permanent joint which is obtained by the fusion of the edges of the two parts to be joined together with or without the application of pressure and filler material. Welding is extensively used in fabrication as an alternative method for casting or forging and as a replacement for the bolted and riveted joints. The Stresses in the welded joints are difficult to determine because of the variable and unpredictable parameters like homogeneity of the weld metal, thermal stresses in the welds, changes of physical properties due to high rate of cooling and overheating. As the weld is weaker than the plate due to slag and blow holes, therefore the weld is given a reinforcement which may be taken as 10% of the plate.

The main considerations involved in the selection of weld type are

- The shape of the welded component required.
- The thickness of the plates to be welded.
- The direction of the forces applied.

Design Specification:

While designing the rivet joint following considerations has been taken as per design databook. The material used for flat plate and rivet is Mild Steel.

Thickness of plate	$t = 6 \text{ mm}$
Size of weld,	$s = 5 \text{ mm}$

CONCLUSION

This study investigated Experimental analysis and Computational Analysis of the elements that contribute to design and analysis of Scarf Lap Riveted And Welded Joint with Different Lap Angle i.e. (2.93° , 3.81° , 5.44°) and Simple Lap Riveted And Welded joint of lapping length i.e. (117mm, 90mm, 63mm). The joints is designed by using Pro-E software. The structural feasibility is analyzed by Finite Element Analysis method. The structure of the Scarf Joint is analyzed using ANSYS (14.5) software. and Pro-E Software is used to generate three dimensional model of Joint.

5.1 Scarf Lap Joint And Simple Lap Joint.

1. As the Lapping length is increasing from 63mm to 117mm and Scarf Lap Angle is decreasing from 5.44° to 2.93° the shear stress develop in both in Simple lap joint And Scarf lap joint gradually increase but more amount of shear stresses develop in Simple Lap joint as compare to Scarf lap joint.
2. As the magnitude of force increases, the shear stress develop in Simple lap joint also increases, but the shear stresses developed Simple lap joint is 15.93 % more than Scarf lap joint.
3. As the Scarf Lap angle decreases from 5.44° to 2.93° failure load increases in Scarf lap joint, same when Lapping length increases from 63mm to 117mm failure load increases.
4. The failure load in Simple Lap Joint is 21.54 % more than Scarf lap joint.
5. The deformation simultaneously strain of object from its original size is decrease.
6. The deformation in Simple Lap joint is more as compare to Scarf Lap joint, Scarf lap joint is more strong and rigid.

5.2 Scarf Lap Riveted Joint & Scarf Lap Welded Joint

1. Scarf Lap Angle is decreasing from 5.44° to 2.93° the shear stress develop in both in gradually increase but more amount of shear stresses develop in Scarf Lap Welded joint as compare to Scarf lap Riveted joint.
2. As the magnitude of force increases, the shear stress develop in Scarf lap welded joint also increases, but the shear stresses developed Scarf lap Riveted joint is 28.92 % less than in Scarf lap welded joint.
3. The failure load in Scarf Lap Riveted Joint is 28.03 % less than in Scarf lap welded joint.
4. The deformation simultaneously strain of object from its original size is decrease for both Scarf lap riveted and welded joint as the lap angle increases from 2.93° to 5.44°
5. The deformation in the Scarf lap welded joint is less, the Scarf lap riveted joint is more rigid and strong.

ACKNOWLEDGMENT

The satisfaction and Euphoria that accompanies a successful completion of any task would be but incomplete without mentioning the people who made it possible whose constant guidance and encouragement crown all the effort with success. I am deeply indebted to all the person who guided during this period helped me in the successful completion of this project. I owe a debt of gratitude and thanks to all of them, who were so generous with their time and expertise.

I acknowledge with great pleasure the guidance and immense support extended by my project Guide Prof. A. B. Dhumne

I would like to sincerely thank to Prof.R.U.Hedau., Head of Mechanical Engineering Department and Prof.R.S.Sakarkar Co-ordinator M.E. Mechanical (CAD/CAM) for their valuable suggestions and support to complete my dissertation report. I am also thankful to our beloved Principal, Dr. S.K. Kalaspurkar, who inspired a lot to achieve the highest goal.
